CS/COE 1550 – Introduction to Operating Systems

Project Overview

Anytime we share data between two or more processes or threads, we run the risk of having a race condition where our data could become corrupted. In order to avoid these situations, we have discussed various mechanisms to ensure that one program's critical regions are guarded from another's. In this project we focus on semaphores and how the OS implements/uses them.

Project Details

Syscalls for Synchronization

We need to create a semaphore data type and the two operations we described in class, `down()` and `up()`. To encapsulate the semaphore, we'll make a simple struct that contains an integer value and a queue of processes:

```
struct cs1550_sem
{
    int value;
    //Some queue of your devising
};
```

We also need two new system calls to operate on our semaphores, with the following signatures:

```
asmlinkage long sys_cs1550_down(struct cs1550_sem *sem)
```

```
asmlinkage long sys_cs1550_up(struct cs1550_sem *sem)
```

Sleeping

As part of your `down()` operation, there is a potential for the current process to sleep. In Linux, we can do that as part of a two-step process.

- 1) Mark the task as not ready (but can be awoken by signals): `set_current_state(TASK_INTERRUPTIBLE);`
- 2) Invoke the scheduler to pick a ready task: `schedule();`

Waking Up

As part of `up()`, you potentially need to wake up a sleeping process. You can do this via:

```
wake_up_process(sleeping_task);
```

where `sleeping_task` is a `struct task_struct` that represents a process put to sleep in your `down()`. You can get the current process's `task_struct` by accessing the global variable `current`. You may need to save these someplace. Look at the book or slides to remember what the process is.

CS/COE 1550 – Introduction to Operating Systems

Atomicity

We need to implement our semaphores as part of the kernel because we need to do our increment or decrement and the following check on it **atomically**. One way to achieve this is to disable interrupts. Given that our OS might be running on a multicore or multiprocessor machine, we'll use *spin locks* for kernel synchronization.

We can create a spinlock with a provided macro:

```
DEFINE_SPINLOCK(sem_lock);
```

We can then surround our critical regions with the following:

```
spin_lock(&sem_lock);
```

```
spin_unlock(&sem_lock);
```

Again, feel free to draw upon the text and handouts for this course as well as your 449 materials.

Adding a New Syscall

To add a new syscall to the Linux kernel, there are three main files that need to be modified:

1. `linux-2.6.23.1/kernel/sys.c`

This file contains the actual implementation of the system calls.

2. `linux-2.6.23.1/arch/i386/kernel/syscall_table.S`

This file declares the number that corresponds to the syscalls

3. `linux-2.6.23.1/include/asm/unistd.h`

This file exposes the syscall number to C programs which wish to use it.

Testing the syscalls

To test your syscalls, use a user-land program. The first thing we need is a way to use our new syscalls. We do this by using the `syscall()` function. Recall that the `syscall` function takes as its first parameter the number that represents which system call we would like to make. The remainder of the parameters are passed as the parameters to our syscall function. We have the syscall numbers exported as `#defines` of the form `__NR_syscall` via our `unistd.h` file (see #3 above)

We can write wrapper functions or macros to make the syscalls appear more natural in a C program. For example, you could write:

```
void down(struct cs1550_sem *sem) {  
    syscall(__NR_cs1550_down, sem);  
}
```

}

Hints

Setting up the Kernel Source (to be done in recitation) using thoth

1. Copy the linux-2.6.23.1.tar.bz file to your local space under /u/OSLab/username
`cp /u/OSLab/original/linux-2.6.23.1.tar.bz2 .`
2. Extract
`tar xvj linux-2.6.23.1.tar.bz2`
3. Change into linux-2.6.23.1/ directory
`cd linux-2.6.23.1`
4. Copy the .config file
`cp /u/OSLab/original/.config .`
5. Build
`make ARCH=i386 bzImage`

You should only need to do this once, however should things go horribly awry you can undo any changes you've made by redoing step 2, which give you a fresh copy of the kernel.

Rebuilding the Kernel

To build any changes you made, from the linux-2.6.23.1/ directory, simply:

```
make ARCH=i386 bzImage
```

QEMU Version

We will be using an x86-based version of Linux and QEMU for this project. The disk image and a copy of QEMU for windows are available on CourseWeb (qemu.zip). For Mac users, you can download an older but GUI-based application (Q.app) available on CourseWeb as well. Point it at the tty.qcow2 disk image in the above zip.

The username and password are both the word **root**.

For Linux users and Mac users wanting to use the homebrew version, you can find on CourseWeb a test version of the disk image and a start.sh script to run it (qemu-test.zip). It should be identical to the above version in terms of functionality, but actually boot with a recent version of QEMU. IF THE ORIGINAL WORKS FOR YOU, DON'T BOTHER WITH THIS ONE.

CS/COE 1550 – Introduction to Operating Systems

On Mac OS X, if you don't have Homebrew, open a terminal and type:

```
/usr/bin/ruby -e "$(curl -fsSL https://raw.githubusercontent.com/Homebrew/install/master/install)"
```

Go through the install steps. When done, install qemu by typing:

```
brew install qemu
```

That will install qemu. Now you can run start.sh from the terminal **in the unzipped folder** to launch qemu.

On Linux, using your appropriate package manager, install qemu-system-arm, likely part of your distro's qemu package.

Then run start.sh **in the unzipped folder** to launch qemu.

Copying the Files to QEMU

From QEMU, you will need to download two files from the new kernel that you just built. The kernel itself is a file named bzImage that lives in the directory linux-2.6.23.1/arch/i386/boot/. There is also a supporting file called System.map in the linux-2.6.23.1/ directory that tells the system how to find the system calls.

Use scp to download the kernel to a home directory (/root/ if root):

```
scp USERNAME@thoth.cs.pitt.edu:/u/OSLab/USERNAME/linux-2.6.23.1/arch/i386/boot/bzImage .
```

```
scp USERNAME@thoth.cs.pitt.edu:/u/OSLab/USERNAME/linux-2.6.23.1/System.map .
```

Installing the Rebuilt Kernel in QEMU

As root (either by logging in or via su):

```
cp bzImage /boot/bzImage-devel
```

```
cp System.map /boot/System.map-devel
```

and respond 'y' to the prompts to overwrite. Please note that we are replacing the -devel files, the others are the original unmodified kernel so that if your kernel fails to boot for some reason, you will always have a clean version to boot QEMU (this is very important to expedite recovery).

You need to update the bootloader when the kernel changes. To do this (do it every time you install a new kernel if you like) **as root** type:

```
lilo
```

lilo stands for Linux Loader, and is responsible for the menu that allows you to choose which version of the kernel to boot into.

CS/COE 1550 – Introduction to Operating Systems

Booting into the Modified Kernel

As root, you simply can use the reboot command to cause the system to restart. When LILO starts (the red menu) make sure to use the arrow keys to select the linux(devel) option and hit enter.

Building and Running test programs

If we try to build your test program using gcc, the <linux/unistd.h> file that will be preprocessed in will be the one of the kernel version that thoth.cs.pitt.edu is running and we will get an undefined symbol error. This is because the default unistd.h is not the one that we changed. What instead needs to be done is that we need to tell gcc to look for the new include files with the -I option:

```
gcc -m32 -o trafficsim -I /u/OSLab/USERNAME/linux-2.6.23.1/include/ trafficsim.c
```

We cannot run our test program on thoth.cs.pitt.edu because its kernel does not have the new syscalls in it. However, we can test the program under QEMU once we have installed the modified kernel. We first need to download the test program using scp as we did for the kernel. However, we can just run it from our home directory without any installation necessary.

File Backups

One of the major contributions the university provides for the AFS filesystem is nightly backups. However, the /u/OSLab/ partition on thoth is not part of AFS space. Thus, any files you modify under your personal directory in /u/OSLab/ are not backed up. If there is a catastrophic disk failure, all of your work will be irrecoverably lost. As such, it is my recommendation that you:

Backup all the files you change under /u/OSLab or QEMU to your ~/private/ directory frequently!

BE FOREWARNED: Loss of work not backed up is not grounds for an extension.

Notes

- printk() is the version of printf() you can use for debugging messages from the kernel.
- In general, you can use some library standard C functions, but not all. If they do an OS call, they may not work

Requirements and Submission

You need to submit:

- The three, also well-commented, files that you modified from the kernel

Make a tar.gz file named USERNAME-project1.tar.gz and upload it to CourseWeb by the deadline.
